```

It seems that this sequence appears to be converging.

b

```
print((1+sqrt(5))/2)
## [1] 1.618034
It shows that the sequence converging to the golden ratio.
\begin{aligned} F_i + F_{i+1} &= F_{i+2} \\ \frac{F_i}{F_{i+1}} + 1 &= \frac{F_{i+2}}{F_{i+1}} \end{aligned}
As we can see that this sequence appears to be converging, then we let \frac{F_{i+1}}{F_i} \to x
then the upper equation can be like
x = 1 + \frac{1}{x}
and we know that x > 0
by solving this equation, we can get that
x = \frac{1 + \sqrt{5}}{2}

```

This function is used to generate all the prime numbers between 2 and n. It works because it will remove all the non-prime numbers in the sequence and add prime number one by one in the loop.

(b)

```
Eratosthenes<-function(n){
    # Print prime numbers up to n (based on the sieve of Eratosthenes)
    if(n>=2){
        sieve<-seq(2,n)

```

[1] 0.7937002

We assume that the function user supplied is monotonic in the domain they give ([i1,i2]), and there is a zero point in the domain ([i1,i2]).

Or if the function is not monotonic, then at the middle of the domain (n=(i1+i2)/2), the function must have a different sign (which means Fun(i1)*Fun(n)<0 or Fun(i2)*Fun(n)<0). Otherwise we don't know whether it has a zero point in the domain.
